For the liquid streams (extracts), we define: $R = A + C$ (kg) $x = C / (A + C)$ undefined (dimensionless) $N = B / (A + C)$ undefined (dimensionless) Note: In the case of clear extracts (complete solid–liquid separation after mixing), $B=0$, hence $N=0$. On the contrary, in turbid extracts, $N>0$.

A simple example of solid-liquid extraction is coffee brewing, which involves the mixing of solid coffee grounds with water. The coffee flavor compounds are extracted from the grounds into the water to form coffee. This video will illustrate the principles of extraction, and demonstrate solid-liquid extraction in the lab through the removal of organochloride residues from soil. Extraction uses the property of solubility to transfer a solute from one phase to another.

Solid-Liquid Extraction | Protocol

Liquid-liquid extraction (LLE) Liquid-liquid extraction (LLE) is based on the transfer of a solute from one liquid phase into another immiscible liquid phase according to differences in solubility. A common analytical challenge is measuring the level of a dilute analyte in a complex aqueous sample matrix, for example blood plasma or wastewater.

Liquid–liquid extraction (LLE), also known as solvent extraction and partitioning, is a method to separate compounds or metal complexes, based on their relative solubilities in two different immiscible liquids, usually water (polar) and an organic solvent (non-polar). There is a net transfer of one or more species from one liquid into another liquid phase, generally from aqueous to organic.

Abstract. Liquid—liquid extraction is a unit operation based on differential solubility of a consolute in two immiscible solvents. This separation technique, also known as solvent extraction, has many successful applications in the pharmaceutical industry because of its inherent flexibility and its suitability for processing heat-sensitive products.
